

METHOD AND SYSTEM FOR UPDATING DATA

ABSTRACT

A method and a system for updating data are proposed, for allowing a user at a client's computer device to monitor data condition in a server, wherein the server includes a data-updating module and a data-reading module, and is pre-constructed with a database and a corresponding result table. First, when a data source transmits data to the server, the transmitted data are stored in the database. When a predetermined data-updating time is reached in operation of the server, the data-updating module retrieves the data from the database and stores the retrieved data in the result table. When a predetermined data-reading time is reached in operation of the client's computer device, a data-reading request is submitted to the server, allowing the data-reading module to read the data in the result table according to the request and transmit the read data to the client's computer device for display.
